# TECHNICAL BULLETIN 

JAMES TAYLOR CHAIR IN LANDSCAPE \& LIVEABLE ENVIRONMENTS

For our analysis, we use a total land use of $490 m^{2}$ with a gross density of 8.25 units/acre for both the front loaded layout (above) and layout with lanes (below). This measure includes a $350 \mathrm{~m}^{2}$ lot plus the share of street, boulevard, sidewalk, and lane (where applicable) for each parcel.

Figure 7-1 (right) Plan view of typical single family residential lot layout along a driveway access street front.

No. 7
January 2001
A Comparison of Street and Backyard Character of Small Lot Single Family Residential using Front Access Driveways versus Rear Access Lanes

## I. Introduction

There is much interest, as well as debate, regarding the relative benefits of providing lane access versus driveway access for family cars owned by residents of homes on small lots. Issues include:

1. the effect on the appearance and safety of the street;
2. the effect on the utility and privacy of the backyard; and
3. the amount of impervious surface attributable to each type.

In this technical bulletin, we provide a comparison of street and backyard characteristics of small lot single family residential with front driveway access versus rear lane access. We have employed a "total land use analysis" for this study that includes the proportionate share of street and lane space attributable to the parcel when computing the parcel size. Thus the total land use for a parcel might include $350 \mathrm{~m}_{2}$ of lot space and $140 \mathrm{~m}_{2}$ of lane and street space. Only by using this method can you get a true comparison of the land area requirements of a particular lot/street/lane arrangement.

## II. Driveway Access Streets

## 1. The effect on the appearance and safety of the street

With driveway access, the street and the sidewalk are frequently crossed by cars to allow direct access to a parking garage or carport. The direct access from a parking garage or carport to the home's entrance of the small lots is a convenience. Nonetheless, driveway crossings reduce the opportunities to plant trees along the roadside boulevard. The curb cuts of the driveway crossings also impact the drainage and infiltration potential of the grass boulevard.

Figure 7-2
Typical view from a sidewalk of a street with front-access lots.

In driveway accessed homes, the garage and parked cars de-emphasize and often obscure the front door and front windows of the home. This can impede views from the house onto the sidewalk and street, reducing the overall sense of "eyes on the street." Driveway crossings increase the level of vehicle/pedestrian conflict on the sidewalk, which leads to an increase in the number of accidents occurring in that zone.

Figure 7-3
Typically, rear yards of street access lots are aligned back to back and separated by a fence.

As shown above in Figure 7-4 and in plan view in Figure 7-5 (right) lanes in the back allow for a continuous uniform sidewalk and street front.
2. The effect on the utility and privacy of the backyard

For the $490 \mathrm{~m}^{2}$ total land use analysis shown here, the total backyard area of driveway accessed lots was $127 \mathrm{~m}^{2}$. Driveway accessed lots are aligned with rear yards and separated by a tall fence on the property line. Backyard views from one home to the next are direct. The elimination of rear yard entry impacts the opportunity to provide rental accommodation in the form of a second-storey coach houses or granny suites. The total distance between rear facades in this example is 17 m .

## 3. The amount of impervious surface attributable to front access lots

The total impervious surface (TIA) for the street access option is approximately $51 \%$. Table 7-1 provides a summary of the impervious surface data for this type of lot.

## III. Lane Access Streets

## 1. The effect on the appearance and safety of the street

Rear-lane lots offer continuous, uniform sidewalk and street fronts, as shown in Figure 7-4 and 7-5. The line of street trees provides continuous canopy cover and shade; the grass boulevard offers a natural surface for drainage and infiltration. The transition from the public sidewalk to the semi-private front yard, demarked in these examples by a picket fence, is clearly distinguished.

Lots with rear lanes provide space for large front porches, and ensure doors and windows are articulated along the sidewalk and street edge. Clear and unobstructed views from the house directly onto the sidewalk and street provide "eyes on the street." The continuity of the street and sidewalk is not disrupted by driveway crossings, which eliminates a vehicle/pedestrian conflict on the sidewalk. The detached rear garage inhibits direct access from a parking garage or car port to a

Figure 7-6
Pedestrian view from a sidewalk along a 'pedestrian dominant' street front.
home's entrance; and, especially during periods of poor weather, can be considered an inconvenience. Examples exist for lots with lanes where the rear garage carport is attached to the back of the home thereby eliminating this concern.

## 2. The effect on the utility and privacy of the backyard

The backyard area for the rear lane access option is summarized on Table 7-2. The rear lane identifies a boundary and provides a transition zone from one private yard to the semi-public lane, to the next private yard. The average distance between rear facades in these lots with rear lanes is 37 m .

Lots with lanes offer access from the back of the property to the rear yard. This can be an important asset for accessing storage, maintaining the house, providing an additional avenue for fire fighters, and when moving. Rear lane lots also provide the opportunity for rental accommodation in the form of second-storey coach houses or granny suites.

## 3. The impervious surface attributable to lots with lanes

The average TIA percent imperviousness for the lanes options is $35 \%$ assuming a permeable, gravel lane. (A paved lane would increase the total impervious surface by $5 \%$.) Table $7-2$ provides a summary of the impervious surface data. In this lot layout, the boulevard between the sidewalk and the street enables infiltration of runoff from the site and provides a continuous planting area for street trees.

## IV. Comparison Summary

Table 7-1 and 7-2 summarize the Lot Dimensions and Layout for Front Loaded Options and Lots with Lanes.

## V. Summary

Rear-lane lots offer uniform sidewalks and street fronts with continuous street tree plantings to provide canopy cover and shade, as well as a continuous grass boulevard for drainage and infiltration. Clear and unobstructed views from the house directly onto the sidewalk and street provide "eyes on the street." The driveway crossings associated with front-loaded lots reduce the overall canopy cover of a street, and may impact the infiltration and drainage potential of the grass boulevard.

Front-loaded lots provide direct access from a parking garage or carport to the home's entrance (which can be beneficial, especially during periods of poor weather) while the rear-lane lot examples (shown in this case with detached garages) do not.

The lots with lanes provide for a larger rear yard with greater distance from neighbouring backyard to backyard, offering a more functional, and private rear yard than those of the front-loaded lot. In summary, based on our analysis, lots with lanes are measurably more efficient, with less overall impermeable surface.
